Abort and kill in simple easy and short way

Abort vs Kill (simple & short):

- Abort = Stop a process/program because of an error or problem. It usually ends itself or is ended due to failure.
  Example: App crashes because of invalid memory access.
- Kill = Forcefully stop a process from outside using user/admin/OS command.
  Example: Using `kill` command in Linux to stop a frozen program.

Short Difference:

Abort = stops because of internal error.

Kill = stopped externally by user/OS.

Any examples

Yes, simple examples:

- Abort: You open Microsoft Word and it crashes because of a corrupted file → program aborts.
- Kill: A browser like Google Chrome freezes, so you close it using Task Manager in Microsoft Windows or `kill` command in Linux → process is killed.
